

**ASSESSMENT OF BAHARIYA HEMATITE - BARITE ORE AS A HEAVY WEIGHT CONCRETE MIX FOR SUBSEA PIPELINE CLADDING****Gaber, M. A.Wahab**Egyptian Petroleum Research Institute, Exploration Department, Nasr City, Cairo, Egypt<sup>1</sup>

---

**ABSTRACT:** *Heavy aggregates of iron ore were imported by petroleum companies in Egypt, for utilization as a major constituent of concrete mix used for coating of offshore petroleum pipelines as a heavy coat for pipeline stability on sea bed and mechanical protection against anchor damages. The hematite -barite heavy aggregates form the main constituents 75% of the concrete mix, with sea water cements and specific water-cement ratio desired to achieve required compressive strength, water absorption and dry density. In earlier studies, author was succeeding to found the Egyptian Ilmenite and Ferro - manganese ores adequate for concrete heavy weight coating of subsea pipelines. This study deals with another substitute of high density aggregates not utilized as economic ore for other valuable purposes, the hematite-barite ore mined and produced by Steel Manufacture Company and not used in steel manufacture due to containing barite ore and low iron content. The laboratory and field tests conducted for the hematite - barite aggregate to ensure that the physical, chemical and mechanical properties complying with coating specification and standards. The hematite - barite heavy aggregate have 3.9 - 4.2 g/cm<sup>3</sup> specific gravity, well graded hematite-barite aggregate, chemically free from detrimental matter. Heavy concrete mix composed from hematite-barite aggregate, sea water cement and fresh water mixed together to produces a concrete mix of 180 -185 pcf (2880 -2964 Kg/m<sup>3</sup>), minimum dry density and compressive strength varying from 40-47 N/mm<sup>2</sup> (400-470 kg/cm<sup>2</sup>), which satisfied the standard specification of submarine pipeline coating.*

**KEYWORDS:** Heavy Aggregate, Concrete Mix, Concrete Cladding, Hematite, Baharya Oasis, Compressive Strength

---

**INTRODUCTION**

Steel Manufacture Company at Baharya Oasis have a large quantity about 3 million tons of hematite ore mixed with a small ration of barite not useful in Steel Manufacture Company looking for using these ore as coating heavy aggregate or drilling fluids materials.

Natural mineral aggregates of high density include aggregates that contain or consist predominately of materials such as barite, magnetite, hematite, ilmenite, and serpentine (ASTM C 637: 1998)<sup>1</sup> & (ASTM – C 638 :1997)<sup>2</sup>. Hematite and Barite has been used as aggregate for heavy weight concrete which is particularly useful in weighting submerged oil and gas pipelines, which would be required to perform the same submerged function. The large pipelines for the Canadian North and Alaska were used a considerable tonnage of Muncho Lake barite for weighting purposes. It is estimated that the total tonnage of weights were 1,000,000 tons costing in the order of \$100 per ton (Jos. F. Hlavay,P.Eng,1970)<sup>3</sup>.

The main target of this study is to find an appropriate local substitute of magnetite and Ilmenite ores, which is used as the main constituent of the concrete mix for concrete cladding

of sub-marine pipelines which specifically demanded in offshore oil and gas fields for transportation of petroleum materials. These heavy aggregates are imported by petroleum companies in Egypt and recently they use the local ilmenite ore instead of imported magnetite and hematite. Laboratory and field application tests disclosed the presence of unexploited hematite - barite deposit in Bahariya Oases mines can be utilized as a heavy aggregate.

The heavy aggregate ores usually occupies about 75% of the total volume of concrete mix, its properties have a definite influence on behavior of hardened and concrete strength; its properties also greatly affect durability (resistance to deterioration under freeze-thaw cycles). The crushing and grading of hematite-barite aggregate shall be conducted as per International standard to achieve the optimum percentages of both fine and coarse aggregates forming the concrete mix and achieving the required strength and density (Gaber, M.AWahab 2013)<sup>4</sup> & (B. Sagar Singh<sup>1</sup>, K.V.Ramana, 2014)<sup>5</sup>.

Concrete weight coating provides negative buoyancy for subsea pipelines, mechanical protection during handling, transportation and laying operations, and protects the line during its lifetime in a marine environment (Fig.1). Hematite - Barite heavy concrete mix is prepared with different specific gravities and thicknesses using high density ores which must be chemically inert, stable and free from detrimental substance to concrete and other key raw materials. It can be applied over anti-corrosion or insulation coatings while the reinforcing wire-mesh is wrapped and incorporated in the concrete coating layer (El Bokle, 1994)<sup>6</sup>.

**Fig. 1: Concrete Weight Coating (CWC) for offshore pipeline**

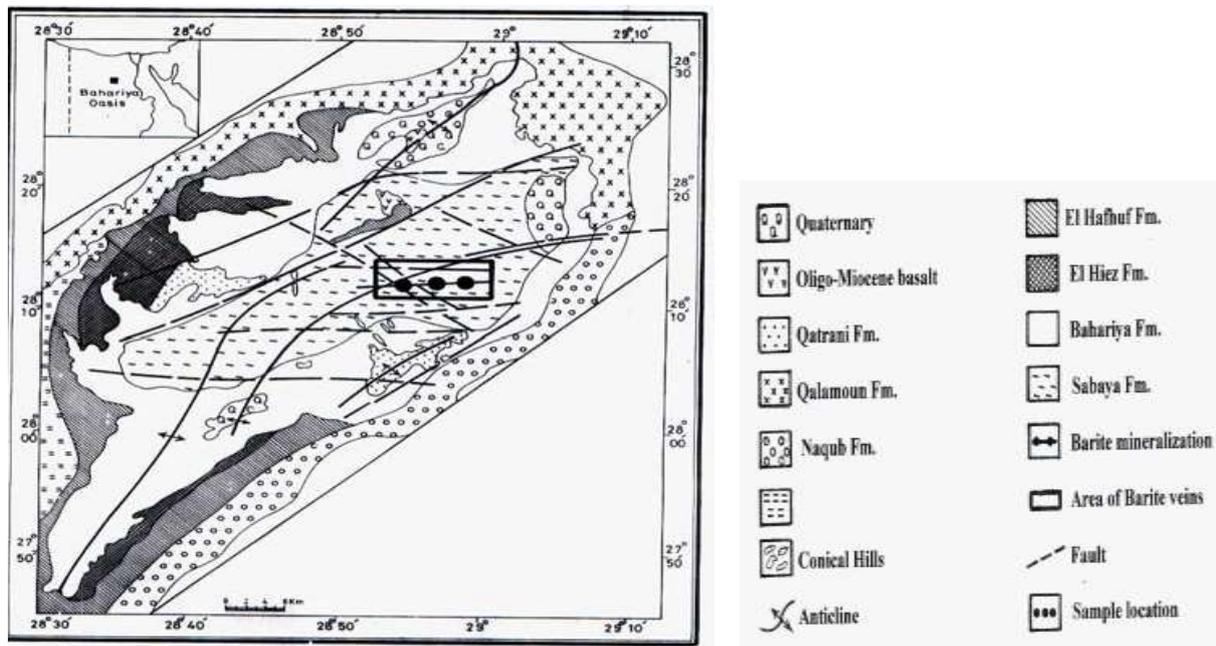

### **Hematite - Barite Occurrence in Bahariya Oasis**

Bahariya iron ore deposits are located in several areas, e.g., El Harra, El Heiz, Ghorabi, El Gedida (Fig.2&3), and Nasser. The iron ore of El Harra belongs to El Harra member of El Haffuf Formation; whereas El Gedida iron ore belongs to Naqb Formation. The area is covered by Bahariya Formation (unfossiliferous varicolored sandstone of Cenomanian age) followed by El Heiz Formation (brownish limestone and sandy clay beds), and El Haffuf Formation of sandstone, sandy clay, and ferruginous beds, which are partly taken by the iron ore deposit, Khuman Formation (chalky limestone), and Naqb Formation of thick limestone beds with few marl and clay associations. The iron content in the ironstone deposits ranges from 30% to 58% Fe, and the manganese content ranges from 0.7% to 7.66% Mn.

The stratigraphic position of Naqb Formation is partly taken by iron ore deposits at El Gedida, El Harra, and Ghorabi; where El Gedida iron ore member belongs to iron deposits of Lower Middle Eocene (Naqb Formation) and the upper Eocene (Abu Maharik Formation. The ore is localized in the crest of anticline (Abdel- Zaher M. Abou Zeid & A. Aziz M. Khalid :2011)<sup>7</sup>.

The El Bahariya Oasis is an oval shaped depression (Fig. 2) trending in a NE-SW direction. Within the depression, the Cretaceous rocks outcrop at its base as well as at the base of the conical hills and the scarp. The Cretaceous rock succession (Sabaya, Bahariya, El Heiz and El Hafhuf Formations) comprises fluvialite to fluviomarine clastics of sandstone, claystone and shale. The Sabaya Formation of Lower Cenomanian age (Morsy, 1987)<sup>8</sup>. is covered by Bahariya Formation which also belongs to the Lower Cenomanian (Soliman and El Badry, 1980)<sup>9</sup>. The Bahariya Formation is unconformably overlain by the Upper Cenomanian fluviomarine marly shale, sandy dolomitic limestone and calcareous sandstone of El Heiz Formation as well as by the Campanian cherty cavernous dolostone, crossbedded sandstone and phosphatic limestone of El Hafhuf Formation.

The barite veins are restricted to the fractures that are parallel to the main E-W or NW-SE striking faults in the Sabaya Formation (Fig. 2). These veins occur sub parallel sets with more than 7 m length and ranging in width between 0.5 to 4 m. They dip 50° towards N, S or NE directions. The barite veins are hard, massive, siliceous and white to gray in color. These veins are numerous and distributed in association with tectonically formed fractures and fissures ( Y. S. Haroun\*, M. F. Raslan, 2010)<sup>10</sup>.

### Experimental and Field Assessment

The aims of present work to study the physical, chemical analysis, mechanical properties, and engineering field testing for high density hematite-barite ore aggregate to be utilized in concrete mix for offshore petroleum pipeline cladding.

**Grading test** was carried out for 10 samples to ensure that the grading is comply with coating specification of Petroleum companies (ASTM - C-33:1986)<sup>11</sup> and (ASTM C-136:1984)<sup>12</sup>. The following diagram (Fig.4), showing the preparation procedure of aggregate samples (AASHTO T 248: 2011)<sup>13</sup>.

**Fig.4 Ore sample quartering for sieve analysis test**

### Aggregate particle shape

Aggregate particle shape and texture affect workability of fresh concrete mix and final production. The ideal aggregate would be spherical and smooth allowing good mixing and decreasing interaction between particles. Shape and texture of coarse aggregates affects the strength of the concrete mix. Increased surface area provides more opportunity for bonding and increases strength. However, excessive surface area in an aggregate can lead to internal stress concentrations and potential bond failure (University of Memphis, Civil 1101, 2009)<sup>14</sup>.

**Specific gravity** is completed for 10 samples. This method covers the determination of apparent specific gravity which pertains to the relative density of solid material making up the constituent particles not including the pore space within the particles that's accessible to water (ASTM-C 128:1979)<sup>15</sup>.

### Chemical analysis test

The XRF analysis was performed for 5 samples of hematite-barite ore taken from Steel Manufacture Company reserve.

**Table (1) Typical physical properties of some heavy weight aggregates**

Material	Chemical Composition	Relative Density	Granular Bulk Density (kg/m <sup>3</sup> )
Geothite	Fe <sub>2</sub> O <sub>3</sub> · H <sub>2</sub> O	3.5–3.7	2100–2250
Limonite	Impure Fe <sub>2</sub> O <sub>3</sub>	3.4–4.0	2100–2400
Barytes	BaSO <sub>4</sub>	4.0–4.6	2300–2550
Illmenite	FeTiO <sub>3</sub>	4.3–4.8	2550–2700
Magnetite	Fe <sub>3</sub> O <sub>4</sub>	4.2–5.2	2400–3050
Hematite	Fe <sub>2</sub> O <sub>3</sub>	4.9–5.3	2900–3200
Ferro phosphorus	Fe <sub>2</sub> O <sub>3</sub> · P <sub>2</sub> O <sub>3</sub>	5.8–6.8	3200–4150
Steel	Fe (scrap iron, steel punchings)	7.8	3700–4650

### Durability (soundness) of Aggregates

Aggregates makeup the largest part of concrete mixes and are responsible for the durability of the mix. Durability is a measure of how well concrete will handle freezing and thawing, wetting and drying, and physical wear. Chemical reactions also can contribute to problems with durability.

Unsound particles: Soft particles such as clay lumps, wood, and coal will cause pitting and scaling at the surface. Organic compounds can be released which interfere with setting and hardening. Weak material of low density which has low wear resistance should also be avoided.

This test is accomplished by repeated immersion in saturated solutions of magnesium sulphate followed by oven drying to partially or completely dehydrate the salt precipitated in permeable pore spaces (ASTM – C88:1983)<sup>16</sup> and (ASTM C-40:1984)<sup>17</sup>.

### Water Absorption of final concrete mix (cubes)

The absorption values are used to calculate the change in the weight of an aggregate due to water absorbed in the pore spaces within the constituent particles compared to the dry condition and the value shall be 5% maximum (ASTM C-642:1982)<sup>18</sup> and (ADMA-OPCO SP-1024, 1993)<sup>19</sup> and (Agip Specification 1987)<sup>20</sup>.

$$\text{Water absorption} = \frac{\text{saturated wt} - \text{Dry wt.}}{\text{dry wt}} \times 100$$

### Dry Density of concrete mix

This test is designed to measure the prepared concrete mix that can produce the suitable dry density necessary for pipeline coating.

### Compressive Strength Test

The main purpose of this test is to ensure that the concrete mix is capable of resist the external forces and shocks that may occur during and after the transportation and laying of the pipe-line undersea water. (B.S. 1881:1983)<sup>21</sup> & (ASTM C-192:1988)<sup>22</sup> and (ASTM C-698:1978)<sup>23</sup>.

## RESULTS AND DISCUSSIONS

### Grading (Sieve analysis) test

Sieve analysis conducted using the equipments (Fig.5), to determine the gradation or distribution of hematite aggregate particle sizes within a standard range and the obtained results are listed in table 2. The grading analysis results indicates that the hematite sample grading plotted within the coating specification range to achieve the required compaction, compressive strength, minimum water absorption and dry density of final concrete mix

**Table 2: Grading analysis of crushed hematite-barite iron ore**

Sieve(mm)	Percentage of passing						Standard
	1	2	3	4	5	6	
9.5	100	100	100	100	100	100	100
4.75	98	97	97	96	97	97	95 – 100
2.36	90	84	85	84	84	85	80 – 100
1.18	70	67	68	68	67	69	50 – 85
0.6	45	42	43	43	41	44	25 – 60
0.3	24	22	23	22	21	23	10 – 30
0.15	7	5	6	6	5	7	2 – 10

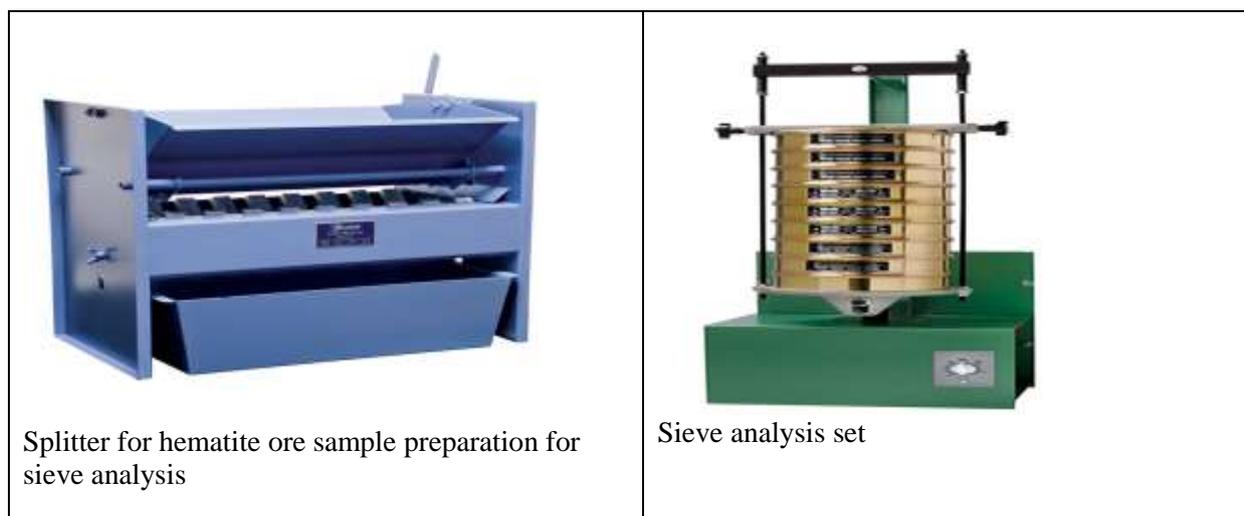

Fig. 5 grading test tools for coarse aggregates

### Aggregate particle shape

The studied hematite –barite aggregate were crushed and graded to rounded sub angular particle shape (Fig.6). Particles surface texture is smooth or rough based on visual judgment, and depends on: rock hardness, grain size, porosity, they affect to workability, paste demand, and initial strength of final concrete mix (Kamran M. Nemati, 2015)<sup>24</sup>

### Specific gravity test

Specific gravity tests (Fig.7), show that the results of selected hematite-barite samples ore grains ranges from 3.9- 4.2 which achieve 180-185 pcf, dry density concrete mix as per listed in table 3.

The following procedure was applied to calculate the ore specific gravity as follows:

- Density of liquid (DL) =  $\frac{D - A}{V}$
- Density of mineral grains =  $\frac{B - A}{(D - A) - (C - B)}$  g/cm<sup>3</sup>
- Specific gravity of the ore aggregate = *Density of ore grain x density of liquid*

Where:

A = weight of empty pycnometer.

B = weight of pycnometer + mineral grain.

C = weight of pycnometer + mineral gain + liquid.

D = weight of pycnometer + liquid.

V = volume of pycnometer.

**Table 3: Specific gravity of hematite-barite aggregate**

Sample No	Specific gravity $\text{g/cm}^3$
1	4.1
2	4.0
3	3.9
4	4.0
5	3.9
6	4.1
7	4.0
8	3.9
9	4.2
10	3.9
Average	4.0

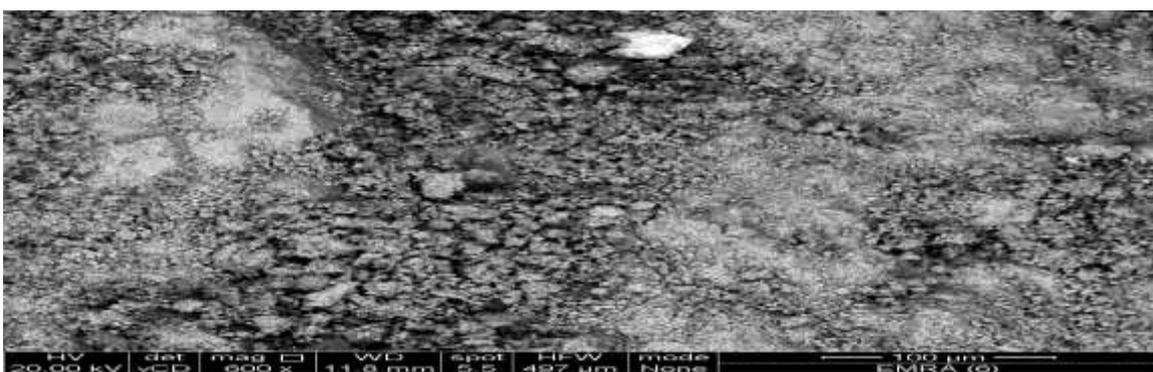

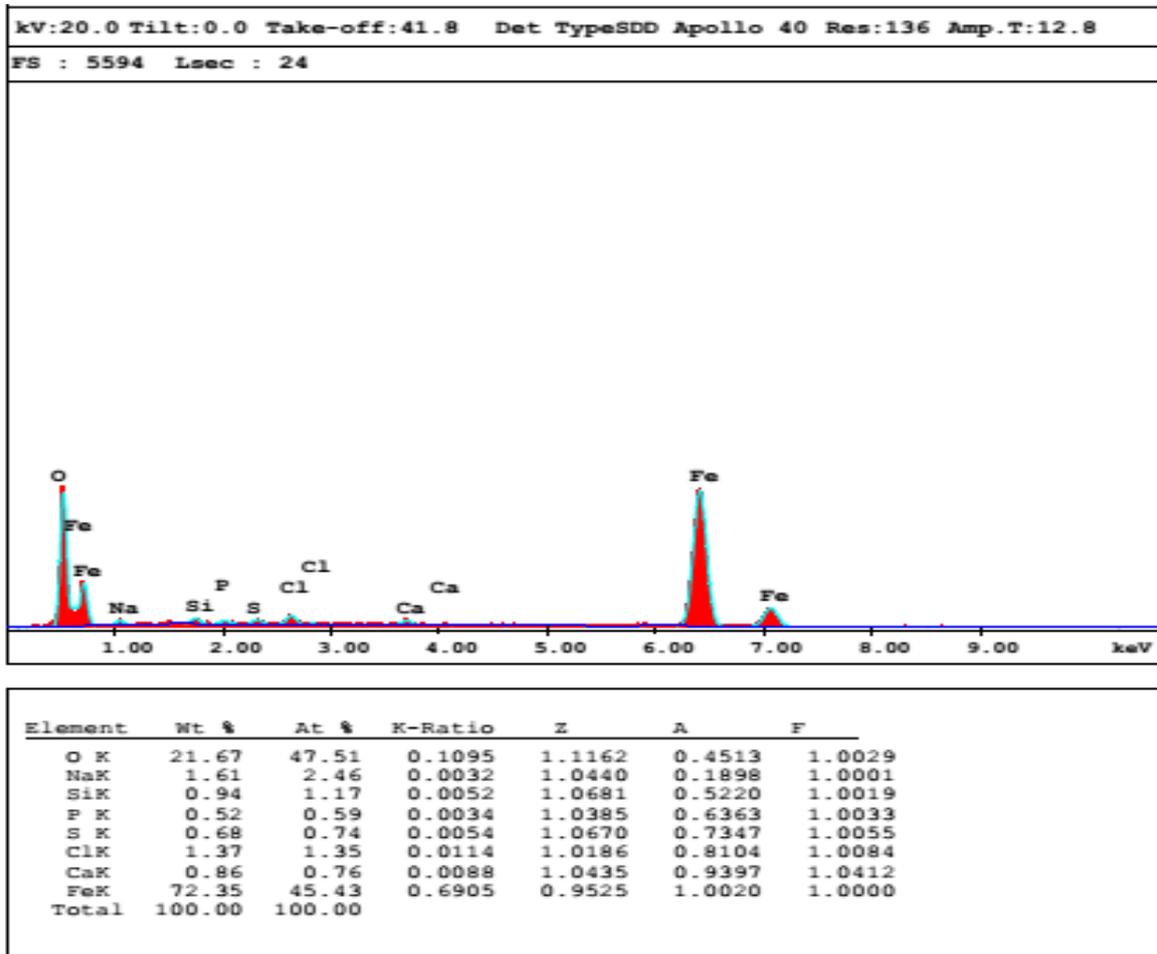

### Chemical analysis

The chemical analysis includes XRF and EDAX analysis of hematite-barite collected sample was conducted at The Egyptian resources Authority and the results illustrated in (Table.4) and (Fig.8), which indicate that the material is mainly composed of  $\text{Fe}_2\text{O}_3$  with 31.35%,  $\text{BaO}$  34.47%,  $\text{SO}_3$  21.48%,  $\text{SiO}_2$  3.94 and  $\text{CaO}$  2.47%.

**Table 4: Chemical analysis of hematite - barite ore**

Constituents	Percentage
$\text{SiO}_2$	4.42
$\text{TiO}_2$	0.18
$\text{Al}_2\text{O}_3$	0.01
$\text{Fe}_2\text{O}_3$	33.35
$\text{MnO}$	0.74
$\text{MgO}$	0.66
$\text{CaO}$	2.47
$\text{Na}_2\text{O}$	0.43
$\text{K}_2\text{O}$	0.16
$\text{P}_2\text{O}_5$	0.46
$\text{Cl}$	0.50
$\text{SO}_3$	19.00
$\text{BaO}$	34.47
LOI	2.73

**EDAX analysis**

**Fig. 8 : EDAX analysis for hematite- barite sample**

**Soundness test of hematite - barite aggregate**

The hematite-barite ore aggregate were subjected to five cycles of titration by using magnesium sulphate to determine the detrimental matter. The difference between the weight of samples before and after the test is the loss % and should be less than 15 % (ASTM-

C88:1983)<sup>16</sup>. The obtained results in table 5 indicate that the ore is sound enough and loss % less than the standard

**Table 5: Results of Soundness test**

Sieve size (mm)	Wt. of sample before test	Wt. of sample after test	Percentage of loss
4.700	100	92	8
2.360	100	91	9
1.180	100	90	10
0.630	100	90	10

### Water absorption of concrete mix cubes

The water absorption was calculated to 10 samples and the ratio is less than 4 %

### Dry density of cubes

The results show that the dry density of cubes ranging from 188 pcf to 195 pcf (3008 – 3120 kg/m<sup>3</sup>), meanwhile the dry density of coupon sample shall be representative approximately 96 % relative compaction of cube results obtained for local hematite-barite concrete mix, accordingly the expected coupon dry density shall be ranging from 180 pcf to 187 pcf, which complying with offshore concrete coating requirement.

### Compressive strength test

There are 20 cubes with dimensions of 15x15x15 cm were prepared using hematite-barite concrete mix (Fig.9), with the following proportion of (75 % ore, 25 % cement, 8% water) and the results are listed in (Table 6) & (Fig.10), which achieved the required compressive strength can resist the handling and barge laying forces and complying with coating specification approved by Petroleum companies.

Preparation concrete mix (hematite-barite ore, sea water cement & water)

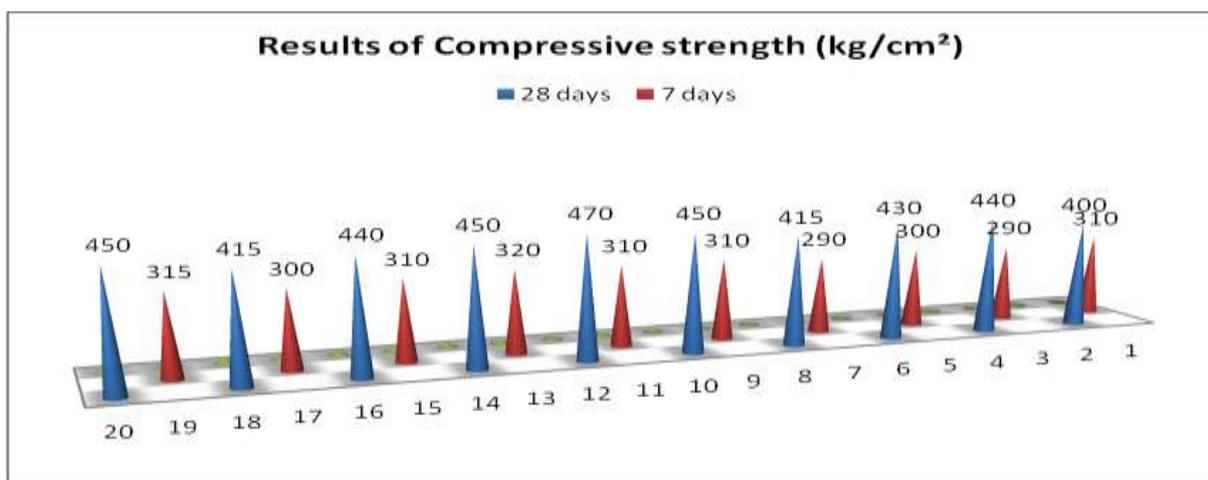

Prepare cube and compaction of concrete mix

17 & 18	300	415
19 & 20	315	450

**Fig.10: Compressive strength of cubes after curing 7 and 28 days**

## CONCLUSIONS

Based on the laboratory tests and field application have been performed to investigate the possibility of applying the Baharyia hematite-barite ore as a heavy weight aggregate forming concrete mix utilized for coating of subsea pipeline, the following conclusions may be drawn.

- The Egyptian hematite iron ore possesses a specific gravity ranging from 3.9 to 4.2.
- The ore produce a concrete dry density ranging from 180 -185 pcf (2884-2964 kg/m<sup>3</sup>).
- The water absorption ration was obtained is below the maximum standard mentioned in coating specification 5% or 8%
- The compressive strength necessary for pipeline cladding was achieved 40-47 N/MM<sup>2</sup> (400 – 470 Kg/cm<sup>2</sup>).
- The ore is a new discovery of high density aggregate for concrete coating purpose of petroleum pipeline.
- The practical coating trial for 3 pipes is required for measuring negative bouncy and coupon density of actual coated sample.

## Acknowledgments

The authors would like to express their gratitude to Steel Manufacture Company team at Baharyia Oasis for help to collect the representative samples, also his thanks to PETROJET, Coating plants team for arrangement and help during filed tests.
